NIP075-2002 simulated and actual to July 19

NIP075-2002 simulated and actual to July 19 - 3 burning days

SLK-031-2002: Simulated and Actual perimeter

SLK031-2002: Simulated and actual perimeters (with spread events)

Introduction	Calibrating fire growth models
Data	MODIS Satellite Hotspots
Model	A logistic regression model for fire spread events based on ISI; extinguishment based on rain
Conclusions	Predicting fire sizes and fire growth days

Introduction

Fire managers report: fires either “run” or don't

Data

Model

During fire “runs” (which we will call spread events), it is very difficult to do fire suppression.

During non-spread events, it is possible.

Conclusions

http://www.nofc.forestry.ca/fire/research/management/fgm/prometheus_e.htm

Introduction

Using FBP or PROMETHEUS requires calibration

Data

NIP075-2002 simulated and actual to July 19

Model

Conclusions

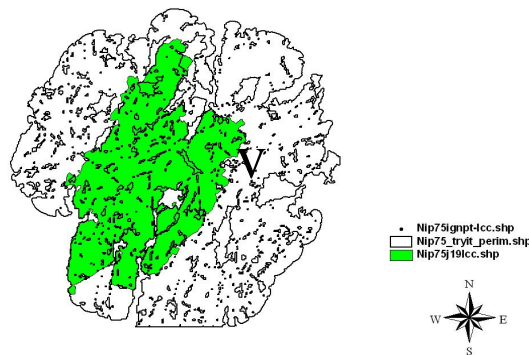

To use PROMETHEUS for multi-day large fire simulations and landscape fire research, it is necessary to identify a sub set of burning days from the start date to the end date.

Introduction

Using FBP or PROMETHEUS requires calibration

Data

NIP075-2002 simulated and actual to July 19

Anderson (2009) suggests several reasons:

The assumption that the whole perimeter is active

The need for diurnal adjustment in litter moisture

Model

We argue for an additional possibility: that the FBP System predicts better at the higher end of fire spread potential, because of the burning conditions during the experimental burns the system is based on.

Conclusions

http://www.nofc.forestry.ca/fire/research/management/fgm/prometheus_e.htm

Introduction

There are several options for calibration

Data

SLK-031-2002: Simulated and Actual perimeter

Anderson (2009) collects several options:

Turn FFMC off at night

Use hourly FFMC (Van Wagner 1977)

Use the diurnal adjustment (Lawson and Armitage 1996)

Use the EMC

Model

Conclusions

We offer another option: the use of the 'spread event' concept.

http://www.nofc.forestry.ca/fire/research/management/fgm/prometheus_e.htm

Introduction

MODIS active fire mapping can find spread events

Data

Model

Conclusions

Assume that when the fires are running, they will be detected by MODIS Aqua or Terra satellite passes.

<http://activefiremaps.fs.fed.us/gisdata.php>

Introduction

Both fire growth days and 'non-growth' days are required

Data

Forest fire records are available from the OMNR, including perimeters – in a few cases, multiple perimeters.

Model

Conclusions

http://www.nofc.forestry.ca/fire/research/climate_change/lfdb/lfdb_map_e.htm

Introduction

Fire weather indices are the independent variables

Data

The OMNR weather stations provide the weather data and indices needed

Model

Conclusions

Introduction

Non-growth days come from satellite data

Data

Start and end dates of fires are recorded, but not 'spread events'. Active fire growth is available through MODIS satellite data.

Model

Conclusions

Introduction

We combine MODIS active fire points with fire perimeter polygons

Data

This includes spatial and temporal merging of data. We also compared it with DFOSS's data on active burning fires.

Model

Conclusions

Introduction

The resulting dataset has growth day/non growth day vs. FWI component

Data

This includes spatial and temporal merging of data. We also compared it with DFOSS's data on active burning fires.

Model

year	mon	day	NUMHOTSPOTS	orgunit	firenum	Final_size	Longitude	Latitude	temp

Model

Conclusions

Introduction

Probability of a growth day depends on FFMC

Data

Model

Conclusions

Introduction

There is some difference between suppressed (blue) and observed (red) fires

Data

Model

Conclusions

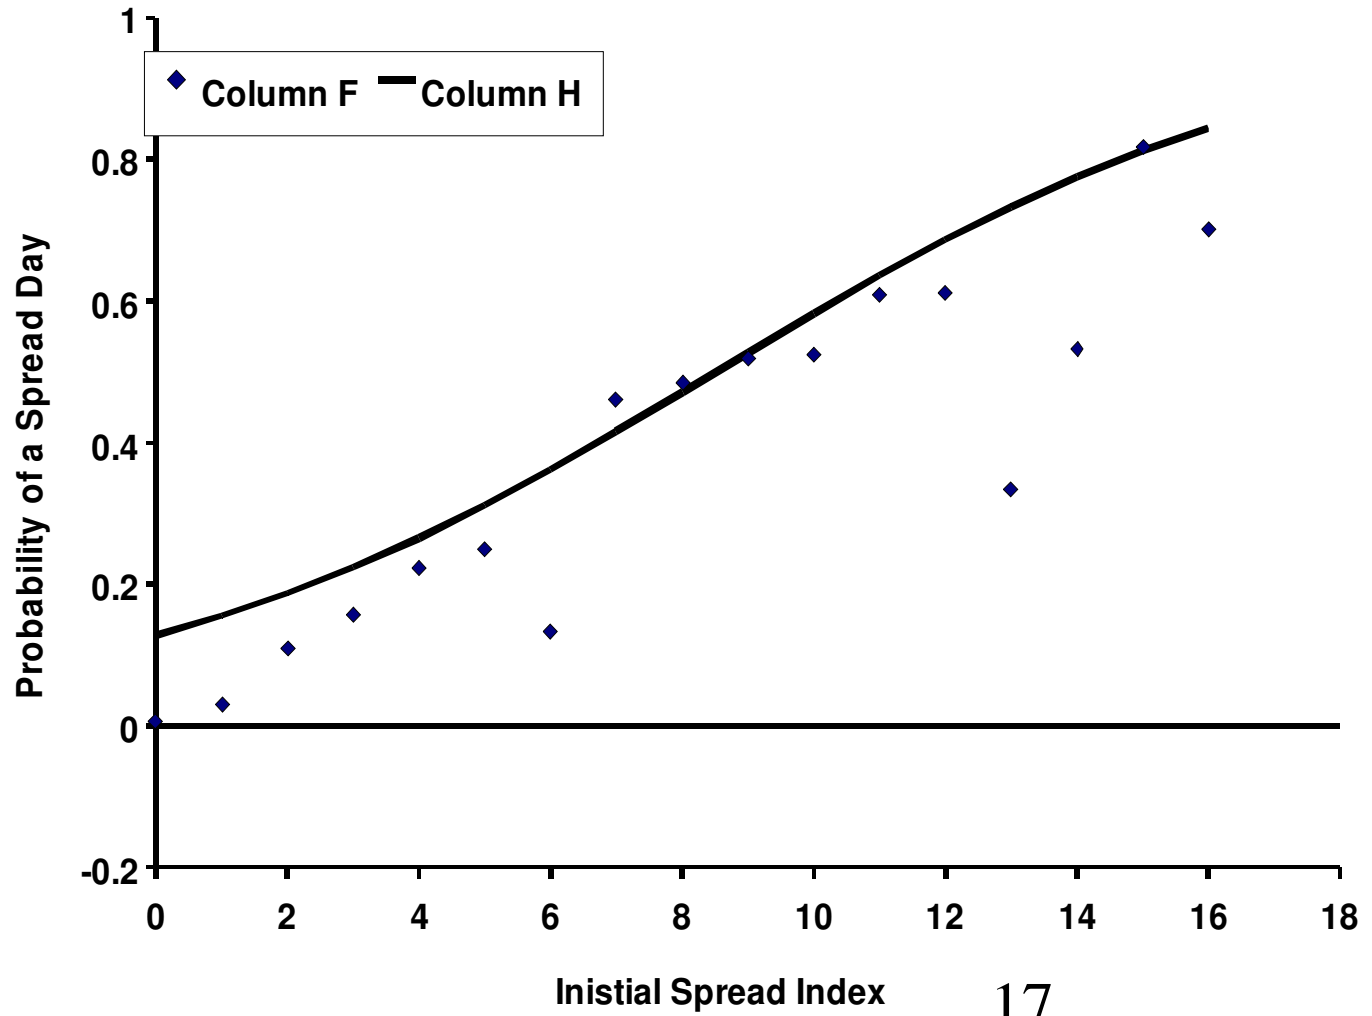

Introduction

Alberta data agree with Ontario data

Data

Model

Conclusions

Introduction

Extinguishment day is the day after the last growth

Data

Definition:

*An extinguishment day is the day after the last growth day.
All prior days could have been extinguishment days.*

Model

Hypothesis:

Extinguishment days should have more rain than prior days.

Conclusions

Introduction

An inch of rain has a 50% probability of being an extinguishment day

Data

Model

Conclusions

Introduction

The number of simulated spread days does vary

Data

Model

Summary of Spread Days

Scenario	Date												# of spread days per scenario:	
	28/04/1999	29/04/1999	30/04/1999	01/05/1999	02/05/1999	03/05/1999	04/05/1999	05/05/1999	06/05/1999	07/05/1999	08/05/1999	09/05/1999		10/05/1999
S1	spread	non spread	spread	non spread	non spread	non spread	spread	spread	spread	spread	non spread	non spread	non spread	6

frequency of occurrence of spread day per date:	3	5	4	2	6	9	9	8	2	6	3	3	0	

Legend
 spread day
 non spread day
 ext days

Conclusions

For CHA001-1999, the numbers of spread events and lengths of spread events varied in the simulation. Note, no extinguishment days.

Introduction

Area burned varies with simulated number of spread days, and which days

Data

For CHA001-1999 (actual size: 19745 ha)

Model

Scenario	Spread days	Area (ha)
S1	6	11129
S2	7	28511
S3	6	27544
S4	6	25152
S5	5	10593
S6	6	17473
S7	6	30128
S8	5	19909
S9	8	38526
S10	5	19909

Conclusions

Introduction

Days are classified as growth; non-growth; and extinguishment days

Data

For DRY 010-2002

Model

Conclusions

Introduction

Days are classified as growth; non-growth; and extinguishment days

Data

For DRY 010-2002

Model

Conclusions

Introduction

There are several benefits to this approach

Data

Unlike the other adjustment methods, spread events can be based on weather variables

Since area burned depends on the number of spread events, the concept can improve area burned predictions

Model

Work is ongoing on applying the spread event and extinguishment models to more historical fires

Conclusions

Introduction

The logistic model gives probability of extinguishment

Data

glm(formula = extdaymodela ~ rain, family = binomial(logit))

Model

Deviance Residuals:

Min	1Q	Median	3Q	Max
-1.8992	-0.3985	-0.3771	-0.3771	2.3147

Coefficients:

	Estimate	Error	z value	Pr(> z)
(Intercept)	-2.60770	0.07307	-35.686	<2e-16 ***
rain	0.10422	0.01111	9.377	<2e-16 ***

(Dispersion parameter for binomial family taken to be 1)

Conclusions

Null deviance: 1951.7 on 3257 degrees of freedom
Residual deviance: 1868.1 on 3256 degrees of freedom
AIC: 1872.1

Introduction

Rain predicts extinguishment best

Data

AIC for Rain: 1872
Coefficient: 0.1
P-value < 2e-16

Model

AIC for Duff Moisture Code (DMC): 1951
Coefficient = 0.008
P-value = 0.04

DC and other indices are similar to DMC

Conclusions

Introduction

Oddly, wind speed did not seem to have an effect on probability of a growth day – this goes against what we know
